From Design to Unreal

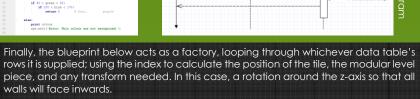

When designing Nebula Knights' modular levels, many maps were exchanged between the team denoting different rooms colour coded to show specific tile properties. Measuring 9 x 17 tiles per room required placing over 150 tiles to see a single room in engine, and with over 50 room designs; building them, if only to visualise the design, became a daunting task. So I wrote a program that would do it for us.

The python program (top right) uses the PyGame library to create a singleton of the LevelMap class with a level map image passed in as an argument. The csv library is then used to return a .csv file of quoted integer values each corresponding to a tile colour defined as a modular level piece within a key (below). Spoofing an initial line denoting the column headers results in a file that Unreal Engine can import as a data table to be interpreted and used in blueprints. Unreal Engine can only import data in the form of quoted .csv files shown in the format below, so the python program works as an adapter for these incompatible data types (maps) and interpreter (Unreal Engine).

Python Map Reader def colour_to_index(colour):... stevelmappi """controlling class for loaded level map"" daf _init__(solt, image_file_to_read, file_to_vrite_to): self_file_eopen(file_to_vrite_to_, 'wb') self_files_eopen(file_to_vrite_to_') wb') self_files_eopen_file_to_read) self_files_eopen_file_to_read) self_files_eopen_file_to_vrite_to_vri

wall rotation needed to face inwards self.tile_rotation = [...] def write_as_cov_file(self):
 """sample the centre of each tile, read the pixel, decide the colour, assign it an in
 edd to = list with its index [n], then writes to the CSV file as a new row"""

Unreal reeds data table starting at index row 1

Spoof initial line of CSV file required by Spool to denote column names csv.writer(self.file, quoting=csv.QUOTE_ALL).writerow(("","levelPiece", "zRotation"))

for x in xrange(self.start_point, self.window_width, self.tile_size):
 for y in xrange(self.start_point, self.window_height, self.tile_size):

if self.corners[n-1] == 3:
 tile_index = 3
else:
 tile_index = colour_to_index(self.window.get_at((x, y)))

level_number_list.append(tile_index)
level_number_list.append(self.tile_rotation(n-1))

print 'Image file to translate must be in folder with this program.'
image file to read - raw_input('Enter The full file name inc extension, and case specific (ie Level_4.JPG): '

print ''
level_reference = raw_input('Enter level reference (one word is level_4): ')

print ''
file_to_write_to = level_reference + '.csv'
orint 'Unreal compatible csv file saved in folder as: ' + file_to_write_to

LevelMap(image file to read, file to write to).write as cav file()

The result is a serviceable mock up of the room (top). Whilst it lacks the personal touch of a hand-crafted designers level (below), it can very quickly help to visualise any of the designer's level maps in engine. Even were they crudely drawn on paper, this program could identify the colour of each tile, and parse the data into a quoted .csv file, which the blueprint could build a room from.
